# Minimax Example

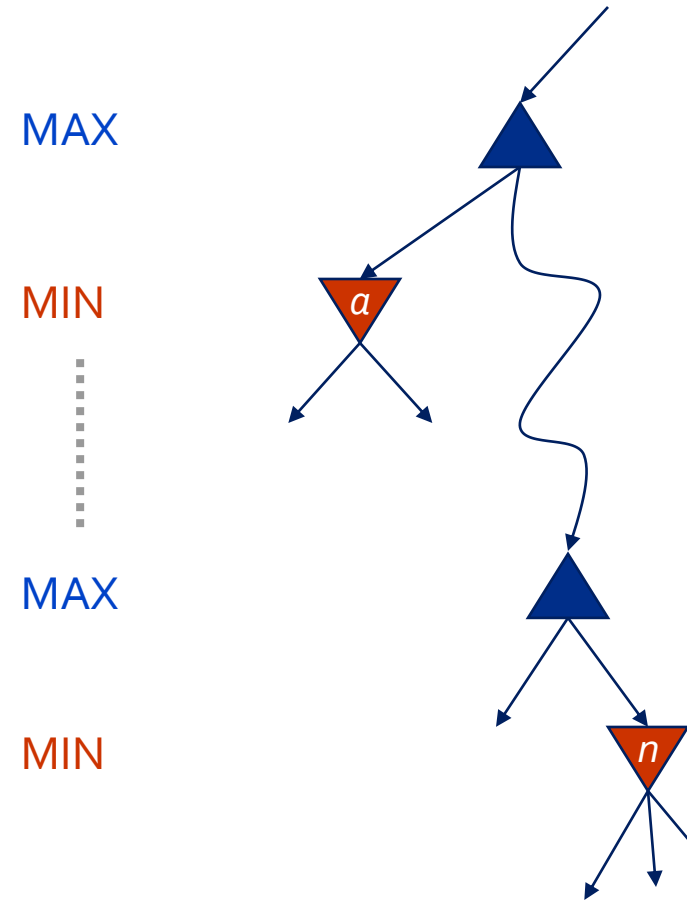

# Minimax Pruning

# Alpha-Beta Pruning

- General configuration (MIN version)
  - We're computing the MIN-VALUE at some node  $n$
  - We're looping over  $n$ 's children
  - $n$ 's estimate of the childrens' min is dropping
  - Who cares about  $n$ 's value? MAX
  - Let  $a$  be the best value that MAX can get at any choice point along the current path from the root
  - If  $n$  becomes worse than  $a$ , MAX will avoid it, so we can stop considering  $n$ 's other children (it's already bad enough that it won't be played)
- MAX version is symmetric

# Alpha-Beta Implementation

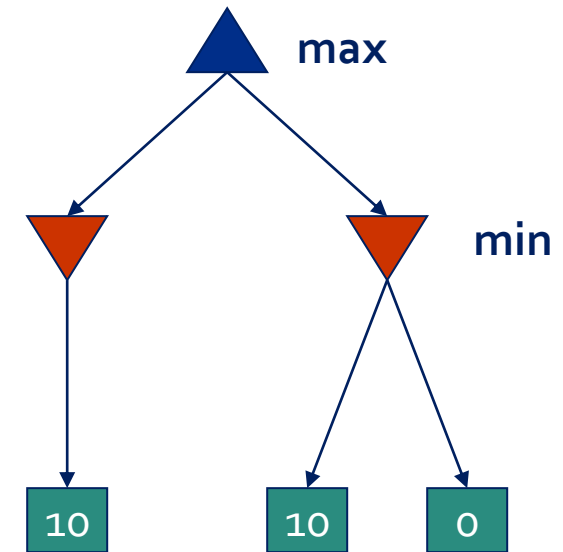

$\alpha$ : MAX's best option on path to root  
 $\beta$ : MIN's best option on path to root

```
def max-value(state,  $\alpha$ ,  $\beta$ ):  
    initialize  $v = -\infty$   
    for each successor of state:  
         $v = \max(v, \text{value}(\text{successor}, \alpha, \beta))$   
        if  $v \geq \beta$  return  $v$   
         $\alpha = \max(\alpha, v)$   
    return  $v$ 
```

```
def min-value(state,  $\alpha$ ,  $\beta$ ):  
    initialize  $v = +\infty$   
    for each successor of state:  
         $v = \min(v, \text{value}(\text{successor}, \alpha, \beta))$   
        if  $v \leq \alpha$  return  $v$   
         $\beta = \min(\beta, v)$   
    return  $v$ 
```

# Alpha-Beta Pruning Properties

- This pruning has **no effect** on minimax value computed for the root!
- Values of intermediate nodes might be wrong
  - Important: children of the root may have the wrong value
  - So the most naïve version won't let you do action selection
- Good child ordering improves effectiveness of pruning
- With “perfect ordering”:
  - Time complexity drops to  $O(b^{m/2})$
  - Doubles solvable depth!
  - Full search of, e.g. chess, is still hopeless...
- This is a simple example of **metareasoning**
  - computing about what to compute
